

## RESOURCE NEGOTIATION IN WIRELESS COMMUNICATIONS NETWORKS AND METHODS

5

### FIELD OF THE DISCLOSURE

10 The present disclosure relates generally to wireless communications, and more particularly to radio resource negotiation in wireless communications networks, for example, data channel requests and assignments in cellular communications networks, and methods.

15

### BACKGROUND OF THE DISCLOSURE

20 In wireless data networks, mobile stations must generally request a data channel assignment before transmitting data. In the CDMA 2000 protocol, for example, the mobile station (MS) requests a data channel assignment by sending a Supplemental Channel Request Message (SCRM) to the network indicating how much data the MS has in its buffer. The channel assignment message from the network in the CDMA 2000 protocol is a Supplemental Channel Assignment Message (SCAM) or an Enhanced Supplemental Channel Assignment Message (ESCAM), which includes  
25 more information. The E/SCAM includes a scheduling period over which the MS may transmit data at an assigned data rate. In the existing CDMA 2000 protocol, the data channel request and assignment messaging occurs at Layer 3 in the architecture.

In the 3<sup>rd</sup> Generation Partnership Project 2 (3GPP2), Technical Specification Group C (TSG-C) Work Group 3 (WG3) has proposed an alternative data scheduling and rate control scheme including overhead channels that may replace the existing E/SCAM. In prior art FIG. 1, under the WG3 proposal, in response to a request message 110 from the MS on the reverse link (RL), the network transmits a scheduling (grant) message 120 on a forward link (FL) Grant Channel (F-GCH). The grant message assigns a data rate, e.g. 76.8 kbits/s, for the MS to transmit one encoder packet. Thereafter, upon successfully transmitting the encoder packet, the MS may continue to transmit data subject to a rate control command sent by the network on the forward link. The rate control command permits the network to adjust the data rate up or down one step at a time, e.g., 1 bit per 10ms frame. The rate control command is sent prior to the frame whose rate it will control. In FIG. 1, the rate control command (RC) 130 sent during frame 140 controls the rate on future frame 142, RC 132 sent during frame 142 controls the rate of frame 144, etc. In the proposed scheme, the data rate may be maintained from one frame to the next.

An alternative proposal by 3GPP2 TSG-C WG3 is a modified grant message having an additional bit to disable the rate control command after transmitting one encoder packet. The effect of disabling the rate command enables the network to limit the data channel assignment to the one encoder packet. Thus, the MS must request a new data channel assignment for transmitting packets in addition to the original encoder packet.

5 In the existing CDMA 2000 data channel assignment protocol,  
the channel assignment is for a fixed period starting at a specified time. In  
the TSG-C WG3 proposals discussed above, the channel assignment is lost  
when there is a gap in transmission. FIG. 1 illustrates loss of the channel  
assignment upon completion of the transmission of data in frame 144, e.g.,  
when the MS buffer is emptied, or upon discontinuous transmission (DTX),  
e.g., for lack of sufficient transmission power due to channel fading. In FIG.  
1, data transmission resumes in frame 146 only upon receipt of a new grant  
122 in response to a new request 112 transmitted by the MS on the reverse  
10 link. Cumulative channel assignment negotiation generally has an adverse  
impact on reverse and forward link capacity and may result latency. The  
CDMA 2000 protocol permits the MS to transmit data without a channel  
assignment, but the data rate is relatively low, on the theory that the  
network has inadequate forewarning, which is necessary to allocate  
15 resources to accommodate the transmission.

The various aspects, features and advantages of the disclosure  
will become more fully apparent to those having ordinary skill in the art  
upon careful consideration of the following Detailed Description thereof  
with the accompanying drawings described below.

## BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 illustrates a prior art data channel request and usage scheme.

5 FIG. 2 illustrates an exemplary wireless communications network.

FIG. 3 is an exemplary process diagram.

FIG. 4 is an exemplary radio resource assignment message.

10 FIG. 5 is an exemplary radio resource request and usage scheme.

## DETAILED DESCRIPTION

15 FIG. 2 is an exemplary wireless communications network 200 comprising a plurality of base stations 210 communicably coupled to a controller 220. A wireless communications device 230 communicates with others devices via one or more base stations when connected to the network. The exemplary network 100 is also coupled to a data server 240, usually by a  
20 gateway not illustrated but known in the art, thus providing data services to wireless communications devices in the network. In one embodiment, the wireless communications network is a CDMA 2000 network, although in other embodiments the network conforms to some other communications protocols, for example, 3<sup>rd</sup> Generation Partnership Project (3GPP) Universal

Mobile Telephone System (UMTS) wireless communications W-CDMA communications systems, among others.

Generally, the communications network allocates radio resources to wireless communications devices in the network. In FIG. 2, for example, one of the base stations 210 serving the wireless communications device 230 assigns radio resources, for example, a data channel assignment and possibly a data rate, to the wireless communications device 230. In some embodiments, the radio resource assignment is made in response to a radio resource request from the wireless communications device, although in other embodiments the request may be implied rather than explicit.

In the exemplary process diagram 300 of FIG. 3, at block 310, a wireless communications device requests a radio resource assignment, for example, a data channel assignment, a dedicated resource, etc. As suggest above, the radio resource assignment request may be implied. In the schematic communications diagram 500 of FIG. 5, the wireless device transmits a request 510 to the network on the reverse link (RL) in the exemplary CDMA 2000 application. In other communications protocols the link on which the wireless device communicates is known by another name, for example, an "uplink" in some WCDMA wireless communications protocols.

In FIG. 3, at block 320, the communications network transmits a radio resource assignment to a wireless communications device, usually but not necessarily, in response to a radio resource assignment request. In one embodiment, the radio resource assignment is communicated to the

wireless communications device in a radio resource assignment, or grant, message, discussed further below. In FIG. 5, the network responds to the radio resource request 510 with a radio resource grant 520 on the forward link (FL), also referred in some communications protocols as a "downlink".

5                   FIG. 4 illustrates an exemplary radio resource assignment message 400 including, in some embodiments, a header portion 410, and a radio resource assignment portion 420, for example, an encrypted data bit field. In the exemplary embodiment where the radio resource assignment is a data channel assignment, the assignment message 400 may include, in at  
10                   least some embodiments, a data rate, or related parameter, assignment field. In FIG. 4, the data rate assignment is also specified in data field 420 of the message. In other embodiments where the message includes a data rate, the data rate may be encoded in a separate field. The format of the exemplary message in FIG. 4 is not specific to any particular communications protocol,  
15                   and is not intended to be limiting. The radio resource assignment and any data rate assignment information included in the message will generally be defined or encoded pursuant a particular communications messaging protocol.

20                   In some embodiments of the disclosure, the network also transmits radio resource assignment time-out information to the wireless communications device, as illustrated at block 330 in FIG. 3. In one embodiment, the radio resource assignment time-out information specifies a duration during which the radio resource assignment to the wireless communications device remains valid after the wireless communications

device discontinues communication on the assigned radio resource. The resource assignment is invalid after the time-out period.

In one embodiment, illustrated in FIG. 4, the radio resource time-out information is included in a time-out duration field 430 in the radio resource assignment message 400, along with the channel and any data rate assignment. Thus radio resource assignment and the radio resource time-out information may be transmitted to the wireless device concurrently in the same message. In other embodiments, however, the radio resource assignment and the time-out information may be transmitted to the wireless device in separate messages. In the exemplary CDMA 2000 application, for example, the channel assignment may be communicated in a radio resource assignment message and the time-out information may be communicated separately in a Layer 3 message.

In one embodiment, the radio resource assignment time-out information is one of a plurality of time-out durations or intervals defined or encoded by one or more bits communicated to the wireless communications device. Generally, the network selects the radio resource time-out interval as a function of one or more variables. In one embodiment, for example, the interval is based on system load and/or load variability. That is, the more load room in the system and the slower the load changes, the larger the grant time-out value. In another embodiment, the radio resource time-out interval is based on the amount of reserve power, or headroom, at the wireless communications device. Alternatively, the interval may be based on the type of traffic and/or quality of service

(QoS). For example, subscribers with a higher quality of service may be provided a longer time-out interval to allow more time to wait for a packet before removing the radio resource assignment.

In embodiments, where the radio resource time-out interval is defined by a single bit, the time-out interval may assume one of two different values, for example, a default duration interval and a zero duration. In another embodiment where the time-out period is defined by a single bit, the time-out period assumes a default value that remains fixed in one bit state and in the other bit state the time-out value assumes a default value that is or may be updated by another message, for example, by a Layer 3 message.

Table I below illustrates another particular example.

**Table I**

1 Bit	Function
0	Grant Expires after the MS transmits one frame.
1	Grant Expires after a gap (time-out time) of X frames, where X is specified by a L3 message.

In Table I, when the time-out bit is set to "0" the radio resource grant expires after the MS transmits a single frame. According to this scheme, with reference to FIG. 5, the radio resource assignment assigned in grant 520

expires upon completion of the transmission of frame 530 when the time-out bit is set to "0" as in Table I.

In Table I, when the time-out bit is set to "1", the time-out duration is set to some default value and the time-out period begins when the wireless communications device discontinues communication on the radio resource, for example, upon discontinuing transmission (DTX) or when the data buffer is emptied. Thus when the time-out bit is set to "1", the radio resource assignment is valid so long as transmission gaps do not exceed the radio resource time-out period. In another embodiment, one or more time-out period values may be stored at the wireless device, and selected when the time-out bit is set to "1", wherein the selection is based on system parameters, as described above.

Alternatively, the radio resource time-out interval may be defined by 2 or more bits mapped to a practical range of time-out intervals as illustrate in Table II below. The exemplary time-out period begins when the wireless device terminates communication, for example, discontinues transmission.

**Table II**

2 Bits	Function
00	1 Frame (approximately 10 ms/frame)
01	4 Frames
10	8 Frames.

11            16 Frames.

---

5            According to Table II, when the time-out bits are set to "00", the MS must  
resume communication on the assigned radio resource within 1 frame  
period. When the time-out bits are set to "01", the MS must resume  
communication on the assigned radio resource within 4 frame periods, etc.  
With 3 bits, the range could be extended to 256 frames. Other values could  
also be used alternatively.

10            In FIG. 3, at block 340, the wireless device communications  
communicates on the radio resource assigned by the network in the radio  
resource assignment, for example, the wireless device transmits data on the  
assigned data channel at the assigned data rate.

15            In FIG. 5, assuming that the time-out interval is greater than 1  
frame, the radio resource assignment assigned by grant 520 remains valid  
during the frame interval 560 during which transmission is interrupted, for  
example, due to a data gap, after transmitting data in frames 530, 540 and  
550. The wireless device is able to resume transmission of data in frame 570,  
after the interval 560, without requesting a new radio resource assignment,  
20            since the frame interval 560 is less than the radio resource time-out interval.  
Similarly, the wireless device is able to resume sending data in frame 590  
after a fading 582 induced transmission interruption in frame 580 without  
requesting a new radio resource assignment, provided the DTX interval 580  
is less than the time-out interval. In either case, of the transmission

discontinuity 560 or 580 is greater than the time-out interval, the wireless device must request a new radio resource assignment before resuming the transmission of frames 570 and 590.

5 In one embodiment, the data rate at which communications are resumed, in the absence of requesting a new radio resource assignment, is not more than the rate at which communications last occurred. In FIG. 5, for example, rate at which transmission resumes in frames 570 and 590 does not exceed the data rate in previous frames 550 and 570, respectively.

10 The use of a radio resource time-out interval enables the network to automatically remove a radio resource assignment when the wireless device to which the resource was assigned fails to communicate, e.g., transmit, for a predetermined time interval, for example, one or more frames. The time-out interval also enables the network to preserve the radio resource assignment when there are short interruption or gaps in the  
15 communications of the wireless communications device, thus reducing the signaling that would be otherwise be required to request and assign a new radio resource to the wireless device. In addition, by enabling the network to dynamically select the radio resource time-out interval, the network may adjust the capacity reserved for the wireless device based on loading  
20 conditions and/or quality of service considerations, as suggested above. For example, in heavy loading situations, or when the channel is changing rapidly, the duration of the grant time-out may be reduced. And in lightly loaded conditions, or where a higher quality of service is required, larger time-out intervals may be provided. Also, when the wireless

communications device has knowledge of the time-out interval, the device may intelligently select transmission times within the window allowed to avoid deep fade, which will reduce power consumption.

5 The radio resource time-out interval of the instant disclosure may also complement existing and proposed radio resource assignment schemes. In FIG. 5, for example, the network sends rate control (RC) commands 522 on the forward link to adjust the data rate assigned at the time of the radio resource assignment.

10 While the present disclosure and what the best modes of the inventions have been described in a manner establishing possession thereof by the inventors and enabling those of ordinary skill in the art to make and use the same, it will be understood and appreciated that there are many equivalents to the exemplary embodiments disclosed herein and that modifications and variations may be made thereto without departing from  
15 the scope and spirit of the inventions, which are to be limited not by the exemplary embodiments but by the appended claims. What is claimed is:
